DR. MIGUEL FONSECA
SILUETY PLASTIC SURGERY

Dr. Fonseca Medical Portal

Executive Proposal, System Overview, and User Guide

A custom medical communication platform for Siluety Plastic Surgery, designed to make patient follow-up clearer, faster, safer, and easier for the care team.

Created by Ramon Diaz, DIT

Prepared May 1, 2026

Executive Summary

What the portal is and why it matters.

The Dr. Fonseca Medical Portal is a custom-built Progressive Web App that connects patients, assigned staff, and administrative leadership in one coordinated care workflow. It is not a template site. It combines mobile chat, staff operations, patient records, prescriptions, media management, internal notes, admin permissions, and deployment-grade infrastructure into one clinical communication system.

The experience is designed to feel familiar to patients, close to WhatsApp/iOS readability, while giving the clinic stronger structure than ordinary messaging apps: patient-specific rooms, care-team assignment, auditability, record organization, and administrative control.

Mobile PWA	A responsive app-like experience designed for iPhone, Android, Safari, Chrome, PWA wrappers, and future app-store packaging.
Clinical chat	Patient and staff chat, message actions, media, audio, call controls, date labels, prescriptions, and patient-safe restrictions.
Admin operations	Patient records, staff permissions, active patients, staff-to-staff private messages, export tools, blocks, audit views, and support workflows.
Database layer	Supabase Postgres tables, authentication, storage, role-based policies, patient links, staff directory, private messaging, push subscriptions, and audit tables.
Release engineering	Vercel deployment, production environment variables, rollback tags, build checks, mobile typography hardening, and iterative QA.

Prepared for Dr. Miguel Fonseca and team. Created by Ramon Diaz, DIT.

Creator Profile

The person behind the system.

Ramon Diaz, DIT created this system using advanced language-model assisted software engineering, modern full-stack development, production database architecture, and deployment workflows.

Professional background presented for this proposal: 10 years at Apple Inc. as a junior developer; VoIP engineering work for PayPal; Bachelor of Science in Software Engineering from New England Institute of Technology; Master's degree from Southern New Hampshire University; and Doctor of Information Technology from Arizona State University.

This project required combining product design judgment, mobile UI engineering, authentication, Postgres/Supabase database modeling, clinical workflow mapping, media handling, security hardening, deployment, and iterative QA. In a commercial software company, this would typically be divided across product, UX, frontend, backend, database, QA, DevOps, and project management roles.

The result is a custom operational system built around the clinic's actual workflow, language needs, mobile device habits, and patient communication requirements.

Project Effort and Value

A conservative engineering-equivalent view.

A project like this is not a simple website. It is a secure, mobile-first clinical operations platform with real database state, role-based behavior, media workflows, patient/staff interfaces, and production deployment requirements.

Product strategy & UX	Patient/staff workflows, Spanish/English language behavior, mobile-first clinical interface	40-70 hours
Frontend engineering	Next.js/React PWA, responsive layouts, modals, chat UI, media handling, app-like safe areas	90-140 hours
Database & security	Supabase auth, Postgres schema, storage, permissions, private messaging, rollback planning	60-110 hours
Admin operations	Control center, staff permissions, patient records, exports, audit/support/legal pages	55-95 hours
Testing & release	Build verification, live deployment, mobile QA, policy/readiness review, rollback tags	35-70 hours
Total equivalent build	A realistic small-team/vendor equivalent for the current system	280-485+ engineering hours

These hours are conservative engineering-equivalent estimates for the current system scope. They do not include the full cost of a traditional agency structure: discovery meetings, account management, UI design rounds, QA cycles, compliance review, deployment support, maintenance retainers, or change orders.

The practical takeaway: this is the type of work a professional software company would price and staff as a serious custom platform build, not as a quick page or simple chat widget.

System Map

How the moving pieces fit together.

Access	Control center, permissions, blocks, audit review	Assigned patient rooms and staff settings	Secure patient link and simplified chat
Communication	Staff-to-staff oversight and export	Patient chat, private staff messages, internal notes	Direct clinic channel, media, calls, prescriptions
Clinical record	Patient profile, procedure, media, export, recovery tools	Internal notes, prescriptions, current medications	Receives care instructions and prescription files
Security	Admin/super admin controls, rollback and audit trail	Assigned team permissions	No admin/privacy/support/delete-account clutter in patient chat

• Patients use a simplified mobile chat experience with calls, media, prescriptions, and readable device-language behavior.

• Staff manage assigned rooms, communicate with patients, add internal notes, send prescriptions, handle media, and contact other staff.

• Admin/Doctor users control team access, view patient lists, review staff-to-staff messages, export records, manage blocks, and support operational oversight.

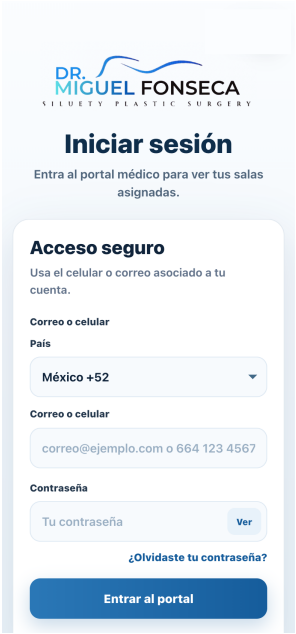
• Supabase stores authentication, patient records, procedures, rooms, messages, staff profiles, audit events, private staff messages, and push notification subscriptions.

• Vercel provides production deployment and environment management for a live app-like web experience.

Access and Sign-Up

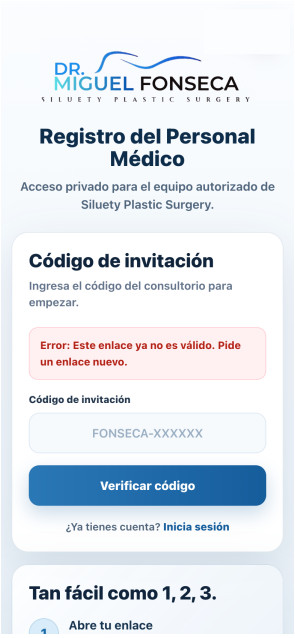
How staff enter the portal and begin using the system.

1. Login



Staff sign in using email or phone, depending on how their account was created.

2. Staff Registration



New team members use an invite code and complete staff onboarding.

3. Office Context

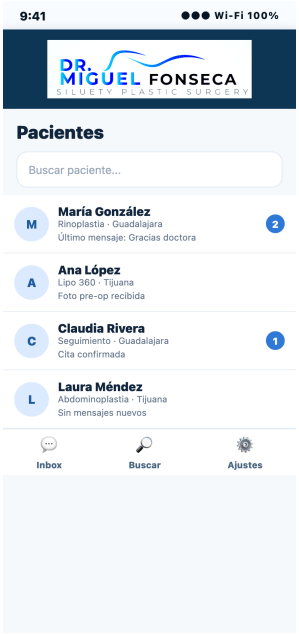
The portal supports clinic context such as Guadalajara and Tijuana workflows.

- Staff accounts are protected by Supabase authentication.
- Invite-code onboarding limits access to approved team members.
- The system supports staff who prefer phone-based access as well as staff who use email.

Staff Workflow

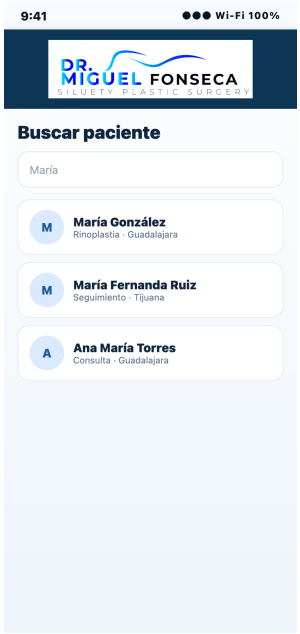
Day-to-day patient communication.

Inbox



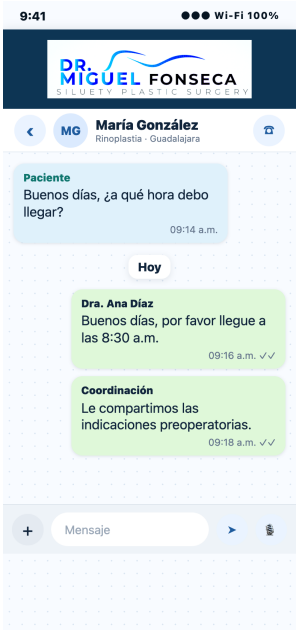
Assigned patient rooms appear in a mobile-first conversation list.

Search



Staff can search by patient, procedure, phone, email, or office context.

Patient Chat



Staff respond in a structured chat environment with patient context visible.

- Each patient room keeps patient messages, staff replies, media, prescriptions, and internal clinical notes tied to the patient record.
- Staff actions are designed for quick mobile use: tap, type, send media, call, open profile, or add notes.
- Messages include timestamps, sender context, and update/delete behavior where permissions allow.

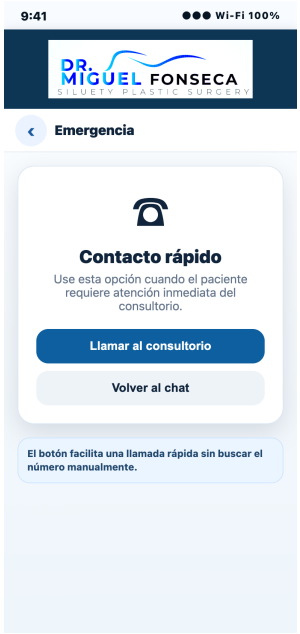
Patient Side

A simple mobile care channel for patients.

Patient Chat

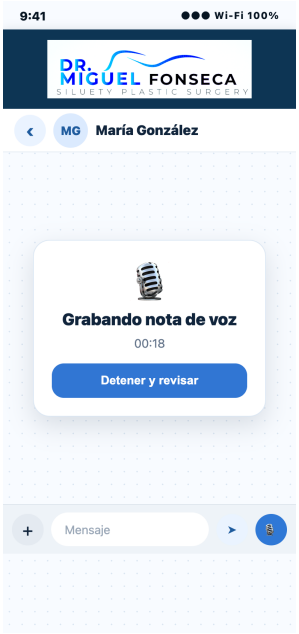
Patients see a focused conversation with readable message text and simple controls.

Emergency / Call



Patients can quickly call the clinic when immediate assistance is needed.

Voice Notes



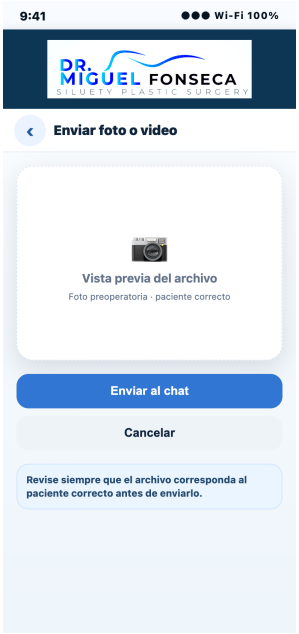
Audio messages allow easier communication when typing is inconvenient.

- The patient view intentionally avoids admin clutter.
- Patient settings are limited to appearance and readability controls.
- Language behavior can align with device/onboarding language so Spanish-only or English-only patients are not blocked by the interface.

Media, Prescriptions, and Files

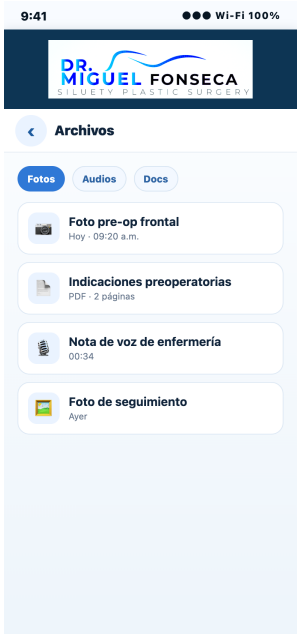
Clinical material stays organized around the patient.

Send Media



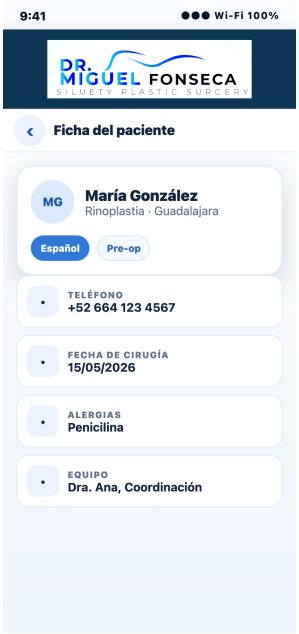
Staff can send patient-related photos, videos, audio, and files from the chat tools.

Files / Prescriptions



Prescription-style files are visible as a distinct clinical resource for the patient.

Profile Media



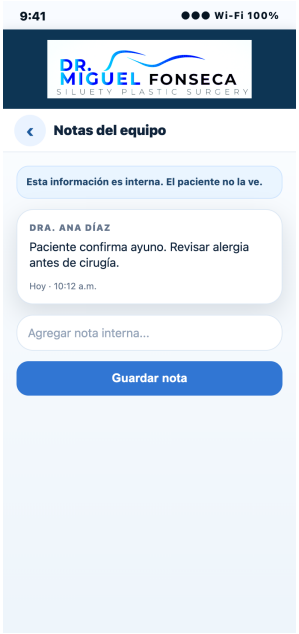
Patient details and related media remain connected to the expediente.

- Recetas/prescriptions are handled as patient-specific clinical material rather than loose general media.
- Patient records can include profile photo, procedure details, office, medications, allergies, and related uploads.
- The prescription viewer includes patient-facing actions such as share, messages, email, and print where supported by the device.

Team Operations

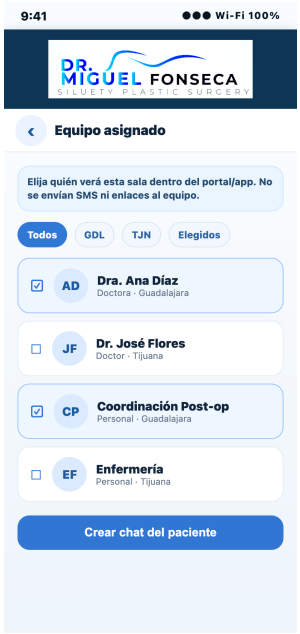
How the clinic coordinates internally.

Internal Notes



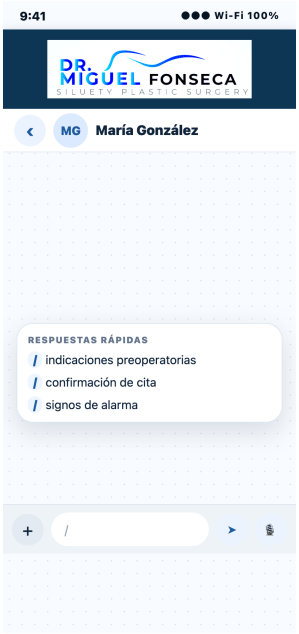
Assigned staff can add internal notes for care coordination.

Team



Assigned team and permission controls support clinical responsibility boundaries.

Quick Replies



Staff can use quick replies for repeated patient communication.

- Internal notes help the assigned team coordinate without exposing those notes to patients.
- Medication and team assignment behavior follows privilege rules: staff can contribute where appropriate, while sensitive deletion/team management is reserved for super admin/doctor roles.
- Staff-to-staff private messaging supports internal communication separate from patient rooms.

Admin / Doctor Control Center

Operational oversight for leadership.

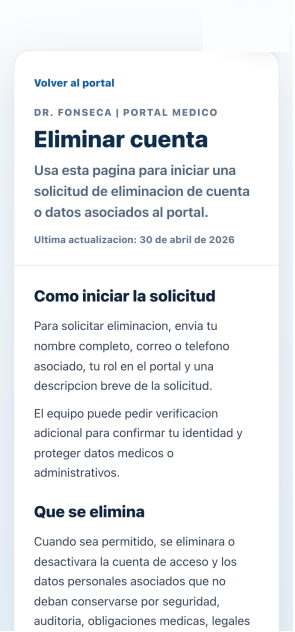
Admin Dashboard

The control center gives leadership visibility into patients, staff, blocks, and internal conversations.

Privacy

The public privacy page supports app-store and patient trust requirements.

Account Deletion



Account/data deletion instructions are available for policy compliance.

- Admin can review active patients, staff-to-staff conversations, team access, blocked signups, and expediente tools.
- Export workflows support sharing or printing conversation and record data through device options.
- Legal/support pages support app review expectations and give patients and staff clear contact paths.

Security and Release Discipline

How the platform is being kept safe.

• Rollback tags are created before risky changes so the project can return to a known safe point.

• Build checks are run before production pushes.

• Production environment variables are managed through Vercel rather than hardcoded in the codebase.

• Push notification endpoints were hardened to require authenticated staff authorization.

• The app uses a mobile-safe global typography and viewport approach for PWA, WebView, and future app-store packaging.

• Remaining release-readiness priority: continue Supabase RLS hardening for patient-room guest access so database policies are as strict as the clinical workflow requires.

Professional note: No software product can guarantee Apple App Store or Google Play approval in advance, because reviewer decisions include account metadata, privacy declarations, screenshots, support URLs, and policy interpretation. This build now has the core ingredients required for a serious submission path: privacy/support/deletion pages, mobile app-like behavior, production hosting, authentication, and a clear clinical purpose.

Closing Position

Why this work has strategic value.

This portal gives the clinic a custom digital care channel that ordinary WhatsApp groups, spreadsheets, and scattered files cannot provide. It centralizes patient communication, creates operational visibility, supports staff accountability, and prepares the clinic for a more polished mobile-app future.

Ramon Diaz, DIT delivered a working production platform by combining advanced AI-assisted engineering, custom UI implementation, database design, deployment operations, and iterative clinical workflow refinement. The value is not only the code. It is the translation of the clinic's real operational needs into a system that patients and staff can actually use.

Recommended next phase: complete Supabase RLS hardening, finalize app-store metadata/screenshots, run staff training, and define a maintenance plan for backups, security reviews, feature requests, and ongoing platform updates.
